Abstract

This paper considers the problem of estimation of population mean when the population median of the study variable is known. Two classes of mean estimators when using information on median of the study variable have been proposed. The expressions for the biases and mean squared errors have been derived up to the first order of approximation. The proposed estimators are compared theoretically with the mean per unit estimator, usual ratio and regression estimators and also with the Bahl and Tuteja (1991), Srivastava (1967), Reddy (1974) and Subramani (2016) estimators. The theoretical findings are validated through some numerical examples as well. It has been shown that proposed estimators perform better than the competing estimators.

Key words: Study variable, Bias, Ratio estimator, Mean squared error, Simple random sampling, Efficiency

1. Introduction

A common approach to parameter estimation is to pick the corresponding sample statistics. It is expected that such estimators will have the desirable properties a good estimator should have. One of the most important properties is that the estimator should have minimum variance, or minimum mean squared error if it biased. Thus, for estimating population mean, most appropriate estimator, in the absence of other information, is the sample mean. Although the sample mean is unbiased for population mean, it has reasonably large amount of variation. Thus, we search for even biased but more efficient estimators having lesser mean squared error as compared to variance of the sample mean. This is achieved through the use of auxiliary variable, which is highly correlated with the study variable. But the drawback of auxiliary information is that it is collected with additional cost of the survey. Thus, in search of improved estimators of population mean, we think of using known population parameters of study variable without increasing the cost of the survey. Median is a parameter which is easily available without having exact information on every unit of population. In this paper our aim is to search for a mean estimator which may be biased but has smaller mean squared errors as compared to the commonly known mean estimators. This is usually done using additional information either on any parameter of the study variable or using an auxiliary variable which is strongly correlated.

with the study variable. We assume the situations where the population mean is unknown but the population median of study variable is known.

Let the finite population under consideration consist of \( N \) distinct and identifiable units and let \( (x_i, y_i), i = 1, 2, \ldots, n \) be a bivariate sample of size \( n \) taken from \((X, Y)\) using a simple random sampling without replacement (SRSWOR) scheme. Here \( Y \) is our study variable and \( X \) is an auxiliary variable. Let \( \bar{X} \) and \( \bar{Y} \) respectively be the population means, and \( \bar{x} \) and \( \bar{y} \) be the corresponding sample means.

Let us consider two interesting examples given by Subramani (2016) where population mean is estimated using information on the population median of the study variable. Although the median is not known, it can be easily guessed from the given data. The tables have been used with permission of the author.

**Example 1:** These concerns the estimation of body mass index (BMI) of the 350 patients in a hospital based on a small simple random sample without replacement.

**Table 1: Body mass index of 350 patients in a hospital**

<table>
<thead>
<tr>
<th>Category</th>
<th>BMI range – kg/m2</th>
<th>Number of patients</th>
<th>Cumulative total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Very severely underweight</td>
<td>less than 15</td>
<td>15</td>
<td>15</td>
</tr>
<tr>
<td>Severely underweight</td>
<td>from 15.0 to 16.0</td>
<td>35</td>
<td>50</td>
</tr>
<tr>
<td>Underweight</td>
<td>from 16.0 to 18.5</td>
<td>67</td>
<td>117</td>
</tr>
<tr>
<td>Normal (healthy weight)</td>
<td>from 18.5 to 25</td>

</tr>
</tbody>
</table>
The median value will be between 90 and 119. One may assume the population median to be approximately 104.5.

2. **Review of Existing Estimators**

The most commonly used estimator of population mean $\bar{Y}$ is the mean per unit estimator, the sample mean $\bar{y}$, given by

$$t_o = \bar{y} = \frac{1}{n} \sum_{i=1}^{n} y_i.$$  

(1)

It is an unbiased estimator and its variance is given by

$$V(t_o) = \frac{1-f}{n} S_y^2 = \frac{1-f}{n} \bar{Y}^2 C_y^2,$$

(2)

where $C_y = \frac{S_y}{\bar{Y}}$, $S_y^2 = \frac{1}{N-1} \sum_{i=1}^{N} (Y_i - \bar{Y})^2 = \frac{1}{N} C_n \sum_{i=1}^{N} (\bar{y}_i - \bar{Y})^2$, $f = \frac{n}{N}$.

Cochran (1940) utilized a positively correlated auxiliary variable and proposed the following ratio estimator

$$t_1 = \frac{\bar{y} \bar{X}}{\bar{x}}.$$  

(3)

Cochran (1940) showed that it is a biased estimator of population mean and he derived the expressions for bias and mean squared error, up to the first order of approximation, given respectively by

$$B(t_1) = \frac{1-f}{n} \bar{Y} [C_x^2 - C_{yx}]$$

and

$$MSE(t_1) = \frac{1-f}{n} \bar{Y}^2 [C_x^2 + C_x^2 - 2 C_{yx}],$$

(4)

(5)

where, $C_x = \frac{S_x}{\bar{X}}$, $S_x^2 = \frac{1}{N-1} \sum_{i=1}^{N} (X_i - \bar{X})^2 = \frac{1}{N} C_n \sum_{i=1}^{N} (\bar{x}_i - \bar{X})^2$, $\rho_{yx} = \frac{Cov(x, y)}{S_x S_y}$,

$$Cov(x, y) = \frac{1}{N-1} \sum_{i=1}^{N} (Y_i - \bar{Y})(X_i - \bar{X}),$$

and $C_{yx} = \rho_{yx} C_y C_x$.

Watson (1937) proposed the usual linear regression estimator of population mean given by,

$$t_2 = \bar{y} + \beta_{yx} (\bar{X} - \bar{x}),$$

(6)

where $\beta_{yx}$ is the regression coefficient of $Y$ on $X$.

He showed that it is an unbiased estimator of population mean. The variance of the above estimator, up to the first order of approximation, is given by,

$$V(t_2) = \frac{1-f}{n} \bar{Y}^2 C_y^2 (1-\rho_{yx}^2).$$

(7)
Bahl and Tuteja (1991) utilized a positively correlated auxiliary variable and proposed the following exponential ratio type estimator of population mean,

\[ t_3 = \bar{y} \exp \left[ \frac{\bar{X} - \bar{x}}{\bar{X} + \bar{x}} \right]. \tag{8} \]

It is a biased estimator and the bias and the mean squared error of this estimator, up to the first order of approximation, are given respectively by

\[ B(t_3) = \frac{1-f}{8n} \bar{y} [3C_x^2 - 4C_{yx}] \quad \text{and} \quad \]

\[ MSE(t_3) = \frac{1-f}{n} \bar{y}^2 \left[ C_y^2 + \frac{C_x^2}{4} - C_{yx} \right]. \tag{9} \]

Srivastava (1967) proposed the following generalized type estimator of population mean,

\[ t_4 = \bar{y} \left( \frac{\bar{x}}{\bar{X}} \right)^\alpha. \tag{10} \]

It is a biased estimator and the bias and the mean squared error of this estimator, up to the first order of approximation, are given respectively by

\[ B(t_4) = \frac{1-f}{n} \bar{y} \left[ \frac{\alpha(\alpha-1)}{2} C_x^2 + \alpha C_{yx} \right] \quad \text{and} \quad \]

\[ MSE(t_4) = \frac{1-f}{n} \bar{y}^2 \left[ C_y^2 + \alpha^2 C_x^2 + 2\alpha C_{yx} \right]. \]

The minimum value of bias and MSE\((t_4)\) for optimum value of \(\alpha = -C_{yx}/C_x^2\) are respectively given by

\[ B(t_4) = \frac{1-f}{n} \bar{y} C_{yx} \tag{11} \]

\[ MSE_{\min}(t_4) = \frac{1-f}{n} \bar{y}^2 C_y^2 (1-\rho_{yx}^2). \tag{12} \]

Reddy (1974) proposed the following class of ratio type estimators of population mean,

\[ t_5 = \bar{y} \left[ \frac{\bar{X}}{\bar{X} + \alpha(\bar{x} - \bar{X})} \right]. \tag{13} \]

It is a biased estimator and the bias and the mean squared error of this estimator, up to the first order of approximation are given respectively by

\[ B(t_5) = \frac{1-f}{n} \bar{y} [\alpha^2 C_x^2 - \alpha C_{yx}] \quad \text{and} \quad MSE(t_5) = \frac{1-f}{n} \bar{y}^2 \left[ C_y^2 + \alpha^2 C_x^2 - 2\alpha C_{yx} \right]. \]

The optimum value of the characterizing scalar is given by \(\alpha = C_{yx}/C_x^2\). The estimator is unbiased for this optimum value of \(\alpha\) and the minimum MSE is given by
Subramani (2016) utilized the population median of the study variable and proposed the following ratio estimator of population mean of the study variable

\[ t_6 = \bar{y} \left( \frac{M}{m} \right). \]  

The bias and the mean squared error respectively of the above estimator, up to the first order of approximation, are given by

\[ B(t_6) = \bar{y} \left[ \frac{1 - \frac{1}{n} \sum \left( \frac{C_m - C_{ym}}{M} \right)}{\bar{y}} \right] \quad \text{and} \]

\[ MSE(t_6) = \frac{1 - \frac{1}{n} \sum \left( \frac{C_m^2 + R_6 C_{ym}^2 - 2 R_6 C_{ym} M}{M} \right)}{\bar{y}^2} \]

where, \( R_6 = \frac{\bar{y}}{M}, \quad C_m = \frac{S_m^2}{M}, \quad S_m^2 = \frac{1}{N} \sum_{i=1}^{N} (m_i - M)^2, \quad S_{ym} = \frac{1}{N} \sum_{i=1}^{N} (\bar{y}_i - \bar{Y})(m_i - M) \quad \text{and} \]

\[ C_{ym} = \frac{S_{ym}}{\bar{y}M}. \]

For the study of the modified ratio type estimators of population mean of the study variable, one may refer to Abid et al. (2016), Subramani (2013), Subramani and Kumarapandiyan (2012, 2013), Tailor and Sharma (2009), Yan and Tian (2010), Yadav et al. (2014, 2015), and Yadav et al. (2016).

3. Proposed Estimators

Motivated by Srivastava (1967), Reddy (1974) and Subramani (2016), we propose two classes of ratio type estimators of population mean using the information on population median of the study variable.

\[ t_{p_1} = \bar{y} \left( \frac{M}{m} \right)^{\alpha}, \quad \text{and} \]

\[ t_{p_2} = \bar{y} \left[ \frac{M}{M + \alpha (m - M)} \right], \]

where \( \alpha \) is a characterizing scalar to be determined such that the mean squared error of the proposed estimator is minimum.

To study the properties of the proposed estimators, the following approximations have been used: \( \bar{y} = \bar{y}(1 + e_0) \) and \( m = M(1 + e_1) \) such that \( E(e_0) = 0, \quad E(e_1) = \frac{M - M}{M} = \frac{Bias(m)}{M} \).
and \( E(e_0^2) = \frac{1-f}{n} C_y^2 \), \( E(e_1^2) = \frac{1-f}{n} C_m^2 \), \( E(e_0 e_1) = \frac{1-f}{n} C_{ym} \), where, \( \bar{M} = \frac{1}{N} \sum_{i=1}^{N} m_i \) (average of sample medians), \( m_i = \) sample median of \( i^{th} \) sample \((i = 1, 2, ..., N)\).

Using the above approximations, \( t_{p_1} \) can be expressed as

\[
t_{p_1} = \bar{Y}(1 + e_0) \left( \frac{M}{M(1 + e_1)} \right)^{1/\alpha} = \bar{Y}(1 + e_0)(1 + e_1)^{-\alpha}.
\]

Expanding the second term of above equation, and retaining terms up to the first order of approximations, we get,

\[
t_{p_1} = \bar{Y}(1 + e_0 - \alpha e_1 - \alpha e_0 e_1 + \frac{\alpha(\alpha-1)}{2} e_1^2) \text{ and}
\]

\[
t_{p_1} - \bar{Y} = \bar{Y}(e_0 - \alpha e_1 - \alpha e_0 e_1 + \frac{\alpha(\alpha-1)}{2} e_1^2).
\]

(20)

Taking expectation on both sides and putting the values of various expectations, we can get the bias of the estimator \( t_{p_1} \), up to the first order of approximation, as given by

\[
B(t_{p_1}) = \bar{Y} \left[ \frac{1-f}{n} \frac{\alpha(\alpha-1)}{2} C_m^2 - \alpha \frac{\text{Bias}(m)}{M} - \alpha \frac{1-f}{n} C_{ym} \right].
\]

Squaring on both sides of (19) and taking expectation, we get the approximate mean squared error of \( t_{p_1} \) as given by

\[
MSE(t_{p_1}) = \bar{Y} \bar{Y} E(e_0^2 + \alpha^2 e_1^2 - 2\alpha e_0 e_1).
\]

Putting the values of various expectations, we have

\[
MSE(t_{p_1}) = \frac{1-f}{n} \bar{Y} \bar{Y} \left[ C_y^2 + \alpha^2 C_m^2 - 2\alpha C_{ym} \right],
\]

which is minimum for \( \alpha_{opt} = \frac{C_{ym}}{C_m^2} \).

The corresponding bias and mean squared error of \( t_{p_1} \) respectively are,

\[
B(t_{p_1}) = -\bar{Y} \left[ \frac{1-f}{n} \left( \frac{C_{ym}^2}{2C_m^2} + \frac{C_{ym}}{2C_m^2} \right) + \frac{C_{ym}}{C_m^2} \text{Bias}(m) \right] \frac{M}{C_m^2}
\]

(22)

\[
MSE_{min}(t_{p_1}) = \frac{1-f}{n} \bar{Y} \bar{Y} \left[ C_y^2 - \frac{C_{ym}^2}{C_m^2} \right].
\]

(23)

Similarly the bias and mean squared error respectively of the other estimator \( t_{p_2} \), up to the first order of approximation, are given by,
\[ B(t_{p_1}) = \bar{Y} \left[ \frac{1-f}{n} \alpha C_m^2 - \alpha \frac{1-f}{n} C_{ym} - \alpha \frac{\text{Bias}(m)}{M} \right] \]

\[ \text{MSE}(t_{p_1}) = \frac{1-f}{n} \bar{Y}^2 \left[ C_y^2 + \alpha^2 C_m^2 - 2 \alpha C_{ym} \right]. \]

The MSE is minimum for \( \alpha_{opt} = C_{ym} / C_m^2 \), and the corresponding bias and mean squared error of \( t_{p_1} \) are respectively given by

\[ B(t_{p_1}) = \bar{Y} \left[ \frac{1-f}{n} \left( C_{ym} - \frac{C_{ym}^2}{C_m^2} \right) - \frac{C_{ym}}{C_m^2} \frac{\text{Bias}(m)}{M} \right] \] (24)

\[ \text{MSE}_{\text{min}}(t_{p_1}) = \frac{1-f}{n} \bar{Y}^2 \left[ C_y^2 - \frac{C_{ym}^2}{C_m^2} \right] \] (25)

It is worth noticing that the minimum mean squared errors of both classes of estimators are same, up to the first order of approximation but the expressions for biases of both the proposed estimators are different. We denote this common minimum mean square error by \( \text{MSE}_{\text{min}}(t_{p_1}) \).

4. **Estimator with Estimated Optimum \( \hat{\alpha} \)**

For situation when values of \( C_{ym} \) and \( C_m \) or their good guessed values are not available, the alternative is to replace them in the optimum \( \alpha_{opt} \) by their estimates \( \hat{C}_{ym} \) and \( \hat{C}_m \) based on sample values and get the estimated optimum value of \( \alpha \) denoted by \( \hat{\alpha} \) as,

\[ \hat{\alpha} = \frac{\hat{C}_{ym}}{\hat{C}_m^2} = \frac{s_{ym}^2}{\bar{y} m^2} \frac{\bar{y} m^2}{s_{ym}^2}. \]

Using the following

\( \bar{y} = \bar{Y}(1+e_0), \quad m = M(1+e_1), \quad s_{ym} = \sigma_{ym}(1+e_2) \) and \( s_m^2 = \sigma_m^2(1+e_3) \) such that \( E(e_0) = 0 \),

\( E(e_1) = \frac{M-M}{M} = \frac{\text{Bias}(m)}{M} \), \( E(e_2) = E(e_3) = 0 \) and \( E(e_0^2) = \frac{1-f}{n} C_y^2 \), \( E(e_1^2) = \frac{1-f}{n} C_m^2 \),

\( E(e_0 e_1) = \frac{1-f}{n} C_{ym}, \ E(e_1 e_2) = \frac{1-f}{n} \mu_{11} \) \( \sigma_{ym} M \) and \( E(e_1 e_3) = \frac{1-f}{n} \frac{\mu_{12}}{\sigma_m^2 M} \),

where, \( \mu_{11} = \sum_{i=1}^{N} (m_i - M)^i (y_i - \bar{y})^i \), and expressing \( \hat{\alpha} \) in terms of \( e_i \)'s \((i = 0, 1, \ldots, 3)\), we have,

\[ \hat{\alpha} = \frac{\sigma_{ym}(1+e_2) \cdot M(1+e_1)}{\sigma_m^2(1+e_3) \bar{Y}(1+e_0)} \]

\[ = \frac{\sigma_{ym} M(1+e_1+e_2+e_0 e_3)}{\sigma_m^2 \bar{Y}(1+e_0+e_3+e_0 e_3)}. \]
After simplification and up to the first order of approximation, we have
\[
\hat{\alpha} = \frac{C_{ym}}{C_{m}^2} (1 - e_0 + e_1 - e_2 + e_3 + e_0^2 + e_0 e_1 + e_0 e_2 - e_0 e_3 - e_1 e_2 - e_1 e_3)
\]  
(26)

From equation (20), putting the value of \( \hat{\alpha} \) in (26) in terms of \( e_i \)'s, up to the first order of approximation, we have
\[
t_{p_1} - \bar{Y} = \bar{Y} \left[ e_0 - \frac{C_{ym}}{C_{m}^2} e_1 - \frac{C_{ym}}{C_{m}^2} \left( e_1^2 - e_1 e_2 + e_1 e_3 \right) \right]
\]  
(27)

Taking expectations on both sides of above equation and putting values of different expectations, we get bias of \( t_{p_1} \) as,
\[
B(t_{p_1}) = -\frac{1 - f}{n} \bar{Y} \frac{C_{ym}}{C_{m}^2} \left[ \frac{Bias(m)}{M} + \left( \frac{C_{m}^2}{\sigma^2 M} + \frac{\mu_{21}}{\sigma^2 M} \right) \right]
\]  
(28)

Squaring on both sides of (27), retaining the terms in \( e_i \)'s up to second order and taking expectations, we get the MSE of \( t_{p_1} \) as,
\[
MSE(t_{p_1}) = \bar{Y}^2 E\left[ e_0 - \frac{C_{ym}}{C_{m}^2} e_1 \right]^2
\]
\[
= \bar{Y}^2 E\left[ e_0^2 + \frac{C_{ym}^2}{C_{m}^4} e_1^2 - 2 \frac{C_{ym}}{C_{m}^2} e_0 e_1 \right]
\]
\[
= \bar{Y}^2 \left[ E(e_0^2) + \frac{C_{ym}^2}{C_{m}^4} E(e_1^2) - 2 \frac{C_{ym}}{C_{m}^2} E(e_0 e_1) \right].
\]

Putting values of different expectations in above equation, we have
\[
MSE(t_{p_1}) = \frac{1 - f}{n} \bar{Y}^2 \left[ C_{y}^2 - \frac{C_{ym}^2}{C_{m}^2} \right]
\]  
(29)

which is same as mean square error of \( t_{p_1} \) for the optimum \( \alpha_{opt} \), that is, the estimator \( t_{p_1} \) based on estimated optimum \( \hat{\alpha} \) attains the same mean square error as that of the estimator \( t_{p_1} \) based on optimum \( \alpha_{opt} \). Same is true for \( t_{p_2} \) as well.

5. Efficiency Comparison

In this section the proposed classes of estimators are compared theoretically with other estimators of population mean considered here and the conditions under which the proposed estimators perform better.

From equation (23) and equation (2), we have
Thus we can see that the proposed estimators are always better than the usual mean per unit estimator of population mean.

From equation (23) and equation (5), we have

\[ MSE(t_1) - MSE_{\text{min}}(t_p) > 0 \text{ if } \frac{C_{ym}^2}{C_m^2} > 0, \text{ or if } C_{ym}^2 > 0. \]

From equation (23) and equation (7), we have

\[ MSE(t_2) - MSE_{\text{min}}(t_p) > 0 \text{ if } \frac{C_{ym}^2}{C_m^2} - C_y^2 \rho_{yx}^2 > 0. \]

From equation (23) and equation (9), we have,

\[ MSE(t_3) - MSE_{\text{min}}(t_p) > 0 \text{ if } \frac{C_x^2}{4} - C_{yx}^2 + \frac{C_{ym}^2}{C_m^2} > 0, \text{ or if } \frac{C_x^2}{4} + \frac{C_{ym}^2}{C_m^2} > C_{yx}. \]

From equation (23) and equation (12), we have,

\[ MSE(t_4) - MSE_{\text{min}}(t_p) > 0, \text{ if } \frac{C_{ym}^2}{C_m^2} - C_y^2 \rho_{yx}^2 > 0. \]

Under the same conditions, proposed estimators are also better than Reddy (1974) estimator of population mean using auxiliary information.

From equation (23) and equation (16), we have,

\[ MSE(t_6) - MSE_{\text{min}}(t_p) > 0, \text{ if } \frac{R_6^2 C_m^2}{2} - 2R_6 C_{ym} + \frac{C_{ym}^2}{C_m^2} > 0, \text{ or if } \frac{R_6^2 C_m^2}{2} + \frac{C_{ym}^2}{C_m^2} > 2R_6 C_{ym}. \]

6. Numerical Study

To validate the theoretical findings, we have considered two natural populations given in Mukhopadhyay (2005) and Koutsoyiannis (1977). In Population 1, the study variable is the quantity of raw materials in lakhs of bales, and the number of laborers is the auxiliary variable, in thousands, for 20 jute mills. Population 2 represents amount of rent in dollars (as study
variable) and number of rooms in the house (as auxiliary variable) in 20 houses of an area in
London. Table 3 presents the parameter values along with various constants. Table 4 presents
biases of various estimators, and Table 5 presents mean squared errors of some of the existing
estimators and the proposed estimators. Percentage relative efficiencies are presented in Table 6.

7. **Results and Conclusion**

In the present study we have proposed two classes of population mean estimators utilizing the information on population median of the study variable itself. The expressions for the bias and mean squared error for both the classes of estimators have been obtained up to the first order of approximation. The optimum values of the characterizing scalars which minimize the mean squared error of the proposed classes of estimators are obtained. For these optimum values of the constants, the minimum values of the mean squared errors of the proposed estimators are also obtained. The proposed estimators are compared with the existing estimators under simple random sampling scheme. The conditions under which the proposed estimators perform better than other existing estimators have also been given. It can be seen from Table 5 that the proposed classes of estimators have smaller mean squared error compared to other mentioned competing estimators. It is worth noting that the Subramani (2016) estimator and the proposed estimators, both of which make use of information on known population median of study variable, perform better than other estimators. But the proposed estimators perform slightly better than the Subramani (2016) estimators for these populations. For other populations where $m$ and $M$ differ significantly, the gains may be better. For highly skewed populations, use of population median may provide even more extensive gains. It may be noticed that while the two proposed classes of estimators have same minimum mean squared error, up to first order of approximation, biases of proposed estimators are not same. For the populations we have used here, absolute bias for proposed estimator $t_{p_2}$ is smaller as compared to $t_{p_1}$.
